

* Gradient descent *

• Gradient descent is a first-order iterative optimization algorithm for finding a local minimum of a differentiable function.

Optimization mean best performance achieve.

• Intuition: we want best fit line

• we try to make minimum loss function

$$L = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

$$\hat{y}_i = mx_i + b$$

$$L = \sum_{i=1}^n (y_i - mx_i - b)^2$$

This formula depends on m & b

mean L is function depend on (m, b)

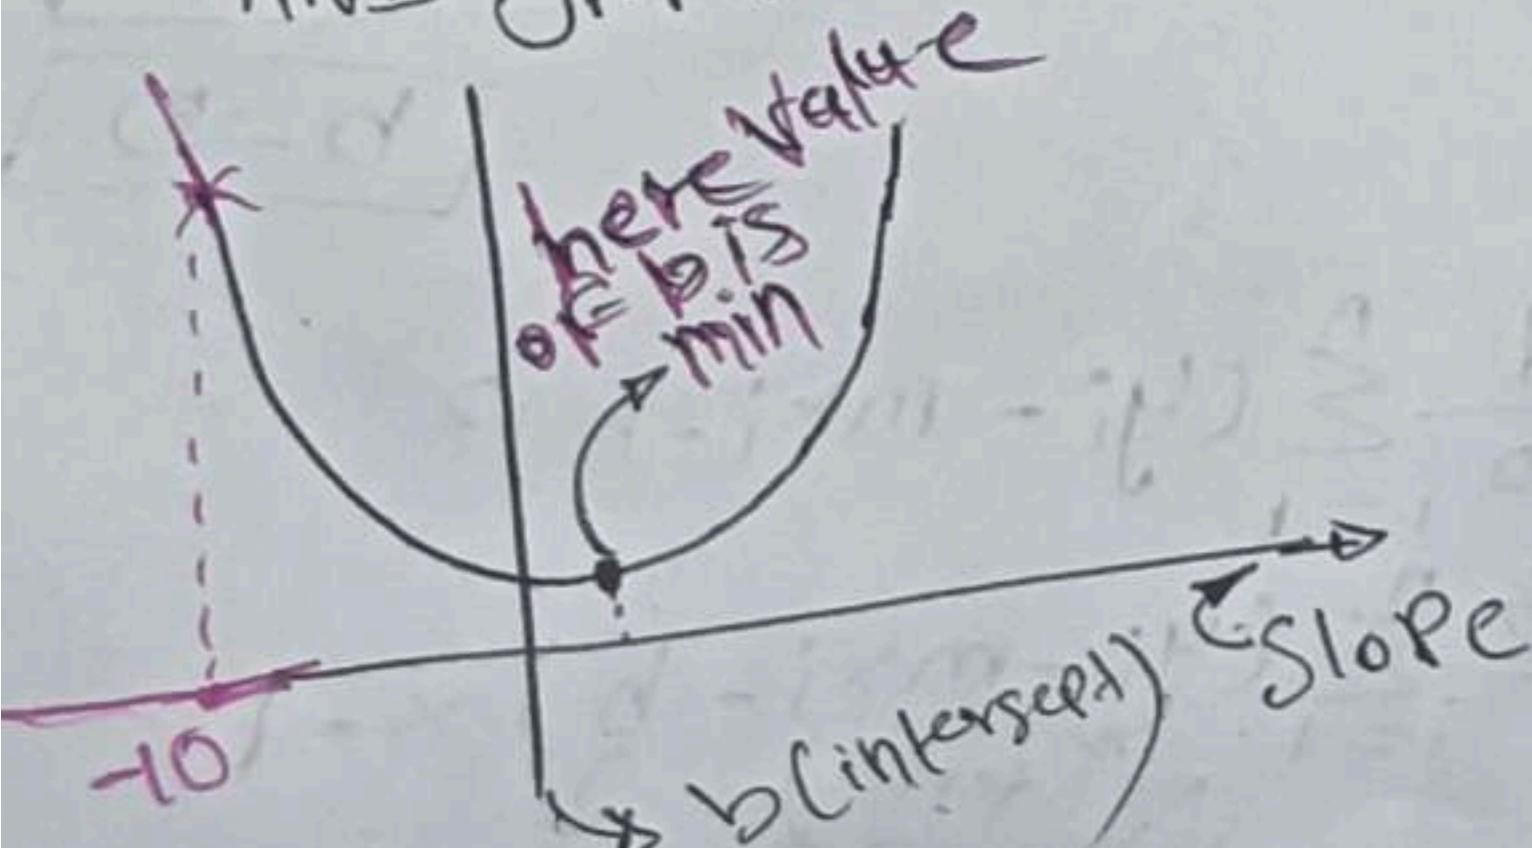

• Suppose our data m value is known to us which is

$$m = 78.35$$

$$L = \sum_{i=1}^n (y_i - 78.35x_i - b)^2$$

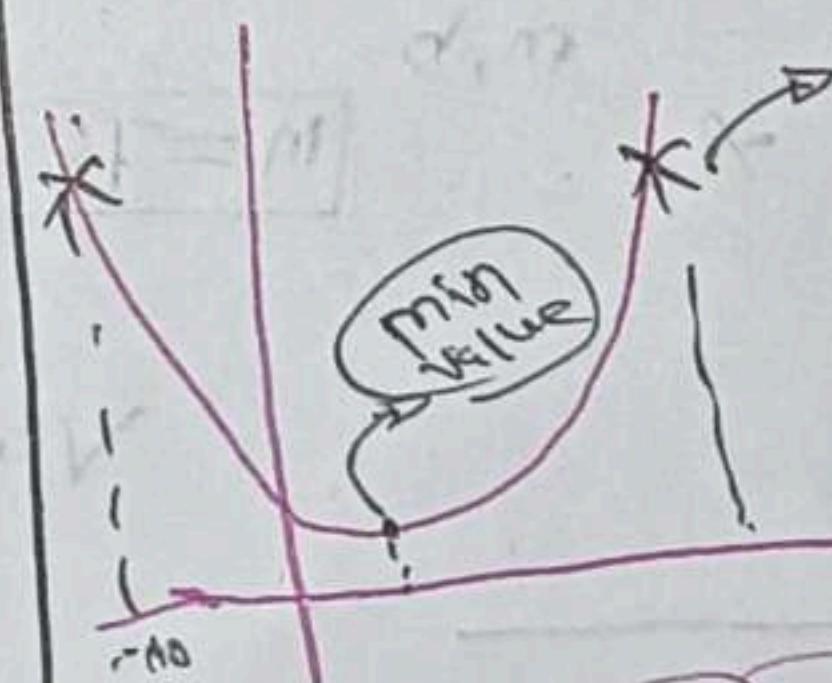

$$L(b) \rightarrow b^2$$

• L and b relationship is depends on square AND graph will be

• Step 1: Select random value of b_{min}

$$b = -10$$

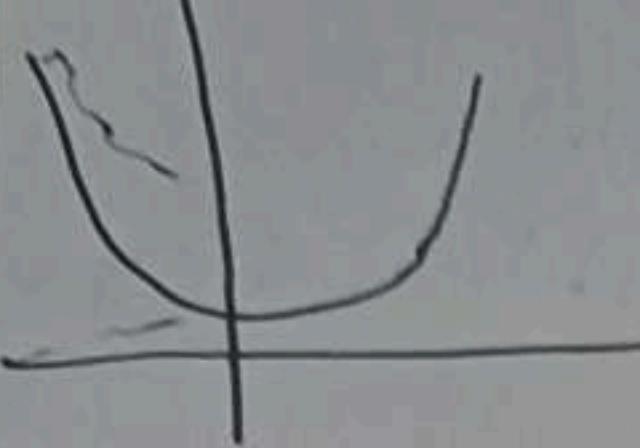

ANS IS STOP FINDING

Understanding of Slop

Slop: It is how line is tilted
Differentiation is a tool to find out slop when graph or function is curv

Ex: $y = x^2$

By differentiating

$$\frac{dy}{dx} = 2x$$

$$\text{slope}(x) = 2x$$

$$x = 1 \text{ slope} = 2$$

$$x = 2 \text{ slope} = 4$$

$$x = -1 \text{ slope} = -2$$

* Slope value will tell us where is minimum value of b

* IF slope is -ve then go forward

* IF slope is +ve then go backward

 $b_{\text{new}} = b_{\text{old}} - \text{slope}$

$$b_{\text{old}} = -10 \quad \text{assume slope}$$

$$b_{\text{new}} = -10 - (-50)$$

$$= -10 + 50$$

$$b_{\text{new}} = 40$$

derivative which depends on two variables like m and b. Both then

it called as gradient or
approximate gradient

Q When to stop?

* $b_{\text{new}} - b_{\text{old}} \rightarrow$ is ~~not~~ becomes very small (0.0000..1)

Then we will stop

* Iteration $\rightarrow 1000, 100, \dots$
Epochs

* Mathematical formulation

$$\begin{array}{c} x \quad x \quad m, b \\ \times \quad \times \\ \hline \end{array}$$

$$m = 78.35$$

* gradient descent
In terms of b

Step 1: Start with a random value suppose $b = b'$
for i in epochs:

$$\eta = 0.01$$

$$b_{\text{new}} = b_{\text{old}} - \eta \times \text{slope}$$

$$b = 0$$

Here we find value of slope

$$L = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

$$\frac{dL}{db} = \frac{d}{db} \left(\sum_{i=1}^n (y_i - \hat{y}_i)^2 \right)$$

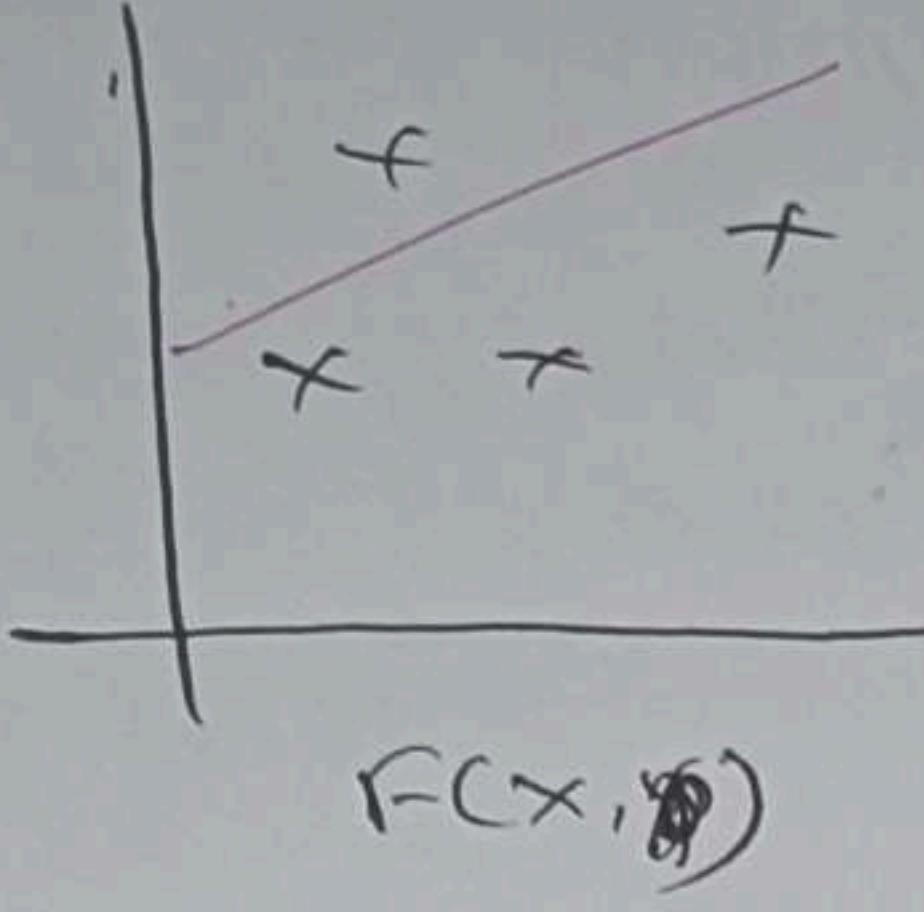

It means
If we change
b then how much
change occurs
in L

$$\hat{y}_i = mx_i + b$$

$$\frac{d}{db} \sum_{i=1}^n (y_i - mx_i - b)^2$$

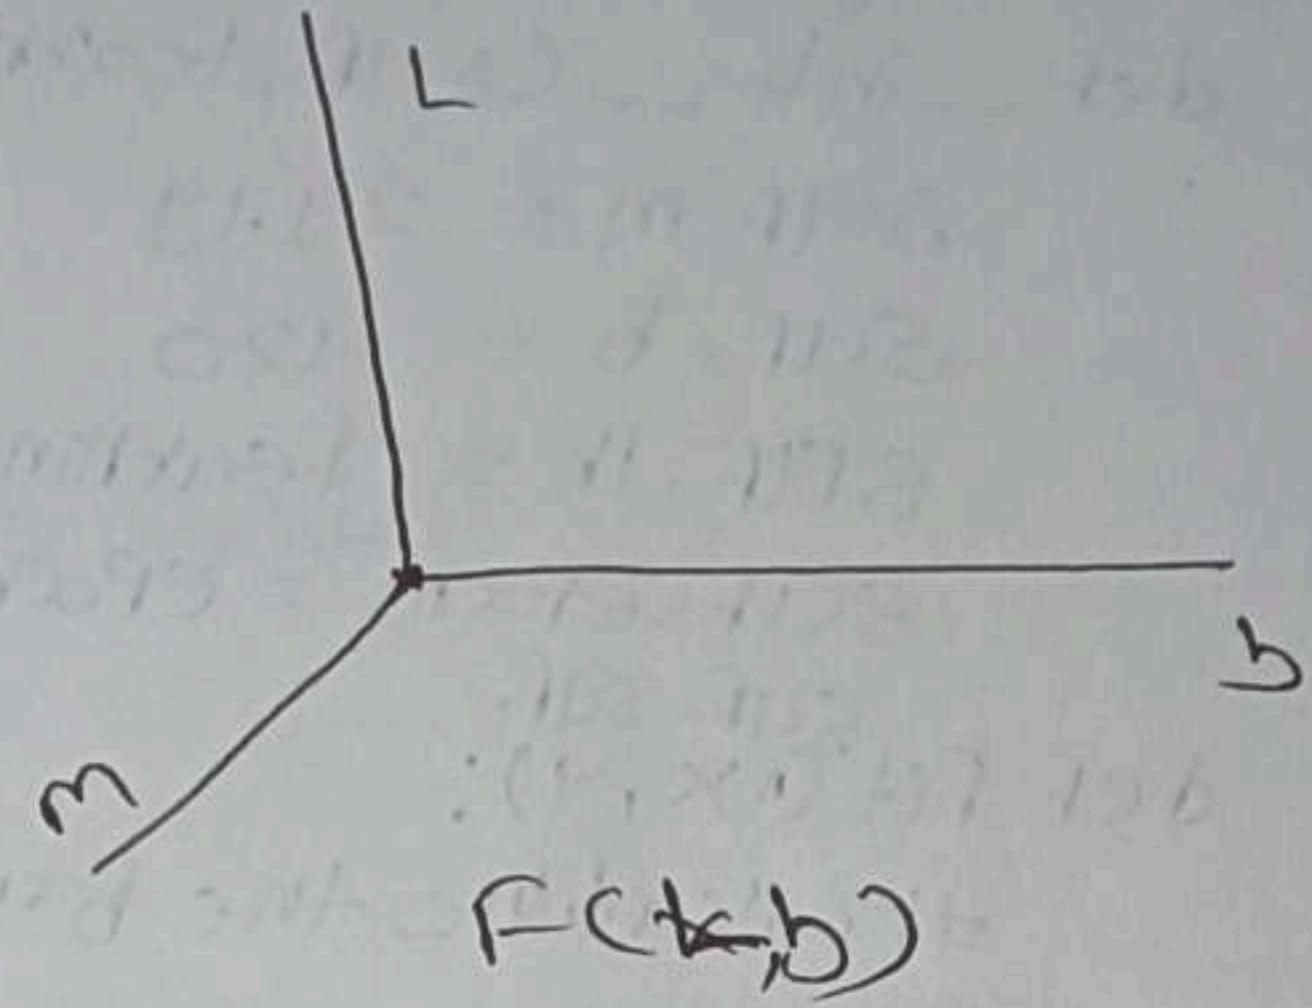

$$2 \sum_{i=1}^n (y_i - mx_i - b) \times -1$$

No b term
it becomes 0

$$L = \sum_{i=1}^n (y_i - \hat{y}_i)^2 = \sum (y_i - mx_i - b)^2$$

$$L(m, b)$$

$$\text{slope}_b = \frac{\partial L}{\partial b}$$

$$\text{slope}_m = \frac{\partial L}{\partial m}$$

$$\sum (y_i - mx_i - b)^2$$

$$\frac{\partial L}{\partial b} = 2 \sum (y_i - mx_i - b)$$

$$\text{slope}_b = -2 \sum (y_i - mx_i - b)$$

$$= \text{slope}_b \text{ at } b=0$$

$$\frac{\partial L}{\partial m} = 2 \sum (y_i - mx_i - b)$$

$$2 \sum (y_i - mx_i - b)$$

$\Delta - n_i$

$$\text{slope}_m = 2 \sum_{i=1}^n (y_i - mx_i - b) x_i$$

$$\text{slope}_m \text{ at } m=1$$

Improvement in code

Now data is little bit change

`X, y = make_regression(n_samples=100, n_features=1,
n_informative=1, n_targets=1,
noise=20, random_state=13)`

$$m = 2g \cdot \lg$$

~~loss~~
n-def GD

Class GDRegressor:

```
def __init__(self, learning_rate, epochs):
```

```
    self.m = 2g \cdot \lg
```

```
    self.b = -120
```

```
    self lr = learning_rate
```

```
    self.epochs = epochs
```

```
def fit(self, X, y):
```

```
# calculate the b using GD
```

```
for i in range(self.epochs):
```

```
    loss_slope = -2 * np.sum(y - self.P(X, range(), self.b))
```

```
    self.b = self.b - (self.lr * loss_slope)
```

```
print(self.b)
```

```
gd.GDRegressor(0.01, 100)
```

(*) Effect of learning rate (*)

$\eta = 0.02 \quad \eta = 0.1 \quad \eta = 0.5$

if very low
then very slow
and more epochs

(*) The universality of Gradient Descent

(*) Now How to calculate m & b

Step 1: initiate random vals for m and b

$m=1$ and $b=0$

② epochs = 100 $lr = 0.01$

for i in epochs:

$b = b - \eta \text{slope}$ } both slopes are different
 $m = m - \eta \text{slope}$

Let's apply Gradient Descent by assuming slope is constant

$$m = 78.35$$

And let's assume the starting value of intercept $b=0$

$$y_{pred} = ((78.35 * x) + 0), \text{ reshape}(4)$$

$$m = 78.35$$

$$b = 0$$

$$\text{loss_slope} = -2 * \text{np.sum}(y - m * x.reshape(4) - b)$$

$$\text{loss_slope}$$

$$\# xslope = loss_slope$$

$$\text{Now we want to do } b_{\text{new}} = b_{\text{old}} - n \times \text{slope}$$

$$n = 0.01$$

$$b = 0$$

$$\text{stepsize} = 0.01 * \text{loss_slope}$$

$$b = b - \text{stepsize}$$

$$b$$

$$\rightarrow 20.92$$

* Now we are making class to calculate only b for now *

from sklearn.datasets import make_regression

import matplotlib.pyplot as plt

import numpy as np

$x, y = \text{make_Regression}(\text{n_samples}=100, \text{n_feature}=1, \text{n_informative}=1,$
 $\text{n_targets}=1, \text{noise}=20)$

plt.scatter(x, y)

Actual result for comparing our result after making own class to calculate b .

from sklearn.linear_model import LinearRegression

lr = LinearRegression()

lr.fit(x, y)

print(lr.coef_)

print(lr.intercept_)

Output:

[29.19] m

[-3.35] b

$$-2 \sum_{i=1}^n (y_i - mx_i - b)$$

This is equation
of slope

for $b=0$ assume $m = 78.35$

$$\text{Slope} = -2 \sum_{i=1}^n (y_i - 78.35 \cdot x_i - 0) = 0$$

Slope ($b=0$)

Code Time:-

From sklearn.datasets import make_regression

import numpy as np

$x, y = \text{make_regression}(n_samples=4, n_features=1, n_informative=1, n_targets=1, noise=80, random_state=13)$

import matplotlib.pyplot as plt.
plt.

plt.scatter(x, y)

→ This is used to make dataset

rows

shape of x

→ output feature

→ n_samples = 4, n_features = 1, n_informative = 1, n_targets = 1, noise = 80, random_state = 13

Randomness
Not Perfect
Linear data

From sklearn.linear_model import LinearRegression

reg = LinearRegression()

reg.fit(x, y)

reg.coef_ → min Slope (m)

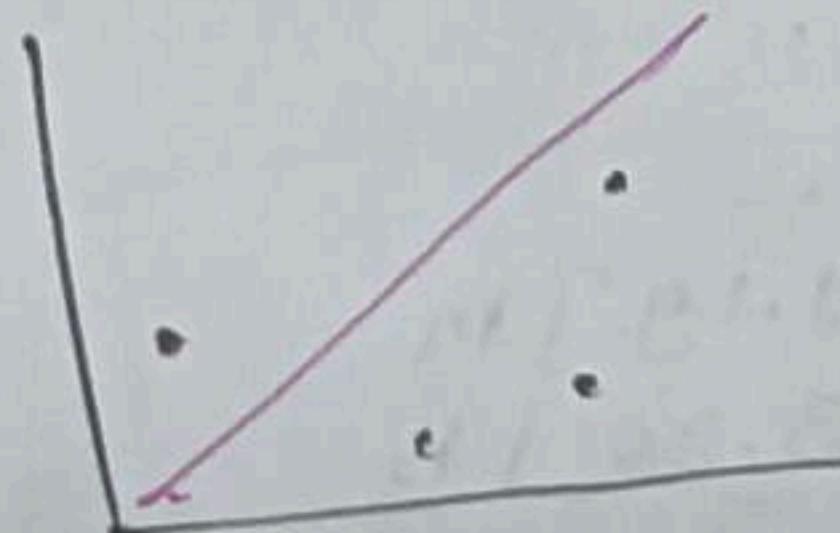

output → 78.35

reg.intercept_

→ 26.1596 → min Intercept value (b)

plt.scatter(x, y)

plt.plot(x, reg.predict(x), color='red')

```

from sklearn.linear_model import LinearRegression
lr = LinearRegression()
lr.fit(X, y)
print(lr.coef_) # Value of m
print(lr.intercept_) # Value of b

```

→ [27.8280] #m
-2.2947 #b

This is calculating to Tally the ans with our class

```

from sklearn.model_selection import cross_val_score

```

```

np.mean(cross_val_score(lr, X, y, scoring='r2', cv=10))

```

Class GDRegressor:

```

def __init__(self, learning_rate, epochs):

```

```

    self.m = 100

```

```

    self.b = -120

```

```

    self.lr = learning_rate

```

```

    self.epochs = epochs

```

```

def fit(self, X, y):

```

```

    for i in range(self.epochs):

```

```

        loss_slope_b = -2 * np.sum((y - self.m * X.ravel() - self.b))

```

```

        loss_slope_m = -2 * np.sum((y - self.m * X.ravel() - self.b) * X.ravel())

```

```

        self.b = self.b - (self.lr * loss_slope_b)

```

```

        self.m = self.m - (self.lr * loss_slope_m)

```

```

    print(self.m, self.b)

```

```

gd = GDRegressor(0.001, 100)

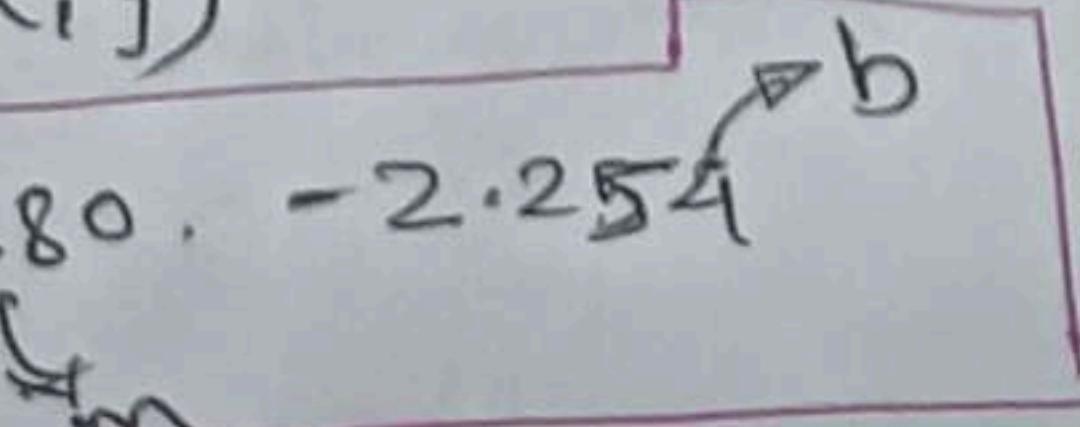

```

```

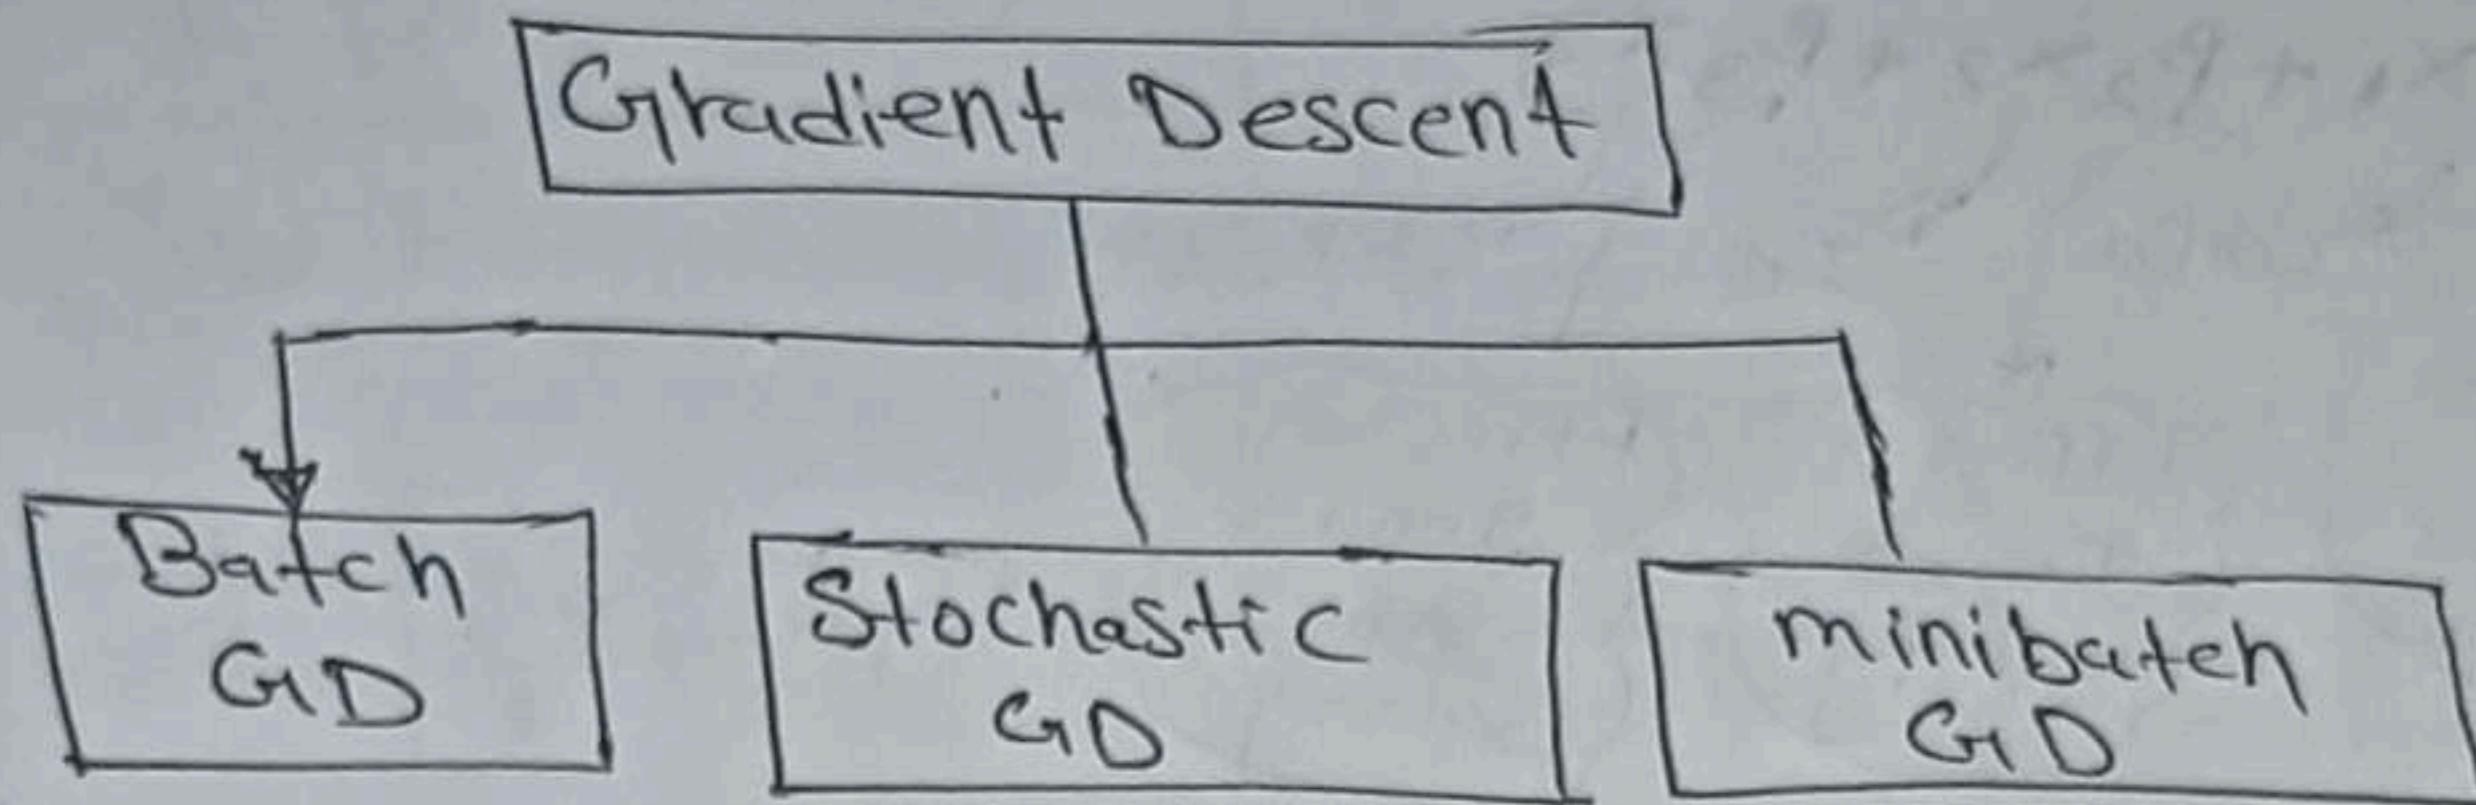

gd.fit(X, y)

```

→ 27.8280, -2.254

④ Types of gradient descent

$$\begin{aligned} m_n &= m_0 - n \times (\text{slope})_m = 0 \\ b_n &= b_0 - n \times (\text{slope})_b = 0 \end{aligned} \quad \left. \begin{array}{l} \text{We update the value of} \\ m \text{ & } b \text{ by viewing all data} \\ \text{This is batch GD.} \end{array} \right\}$$

④ Stochastic GD

• In this we update the values of m & b by viewing single row.

• This is Fast

• Suitable for big/large data

④ Mini batch GD

• Fixed Batch Size

• If data is of 300 rows and batch size = 30
Our values of m & b will change after 30 rows not after full data.

• We already learn batch gradient descent to understand
gradient descent for two variables

we learn for: Giga | Ipa

Now we are learning Batch gradient descent for more than two variable

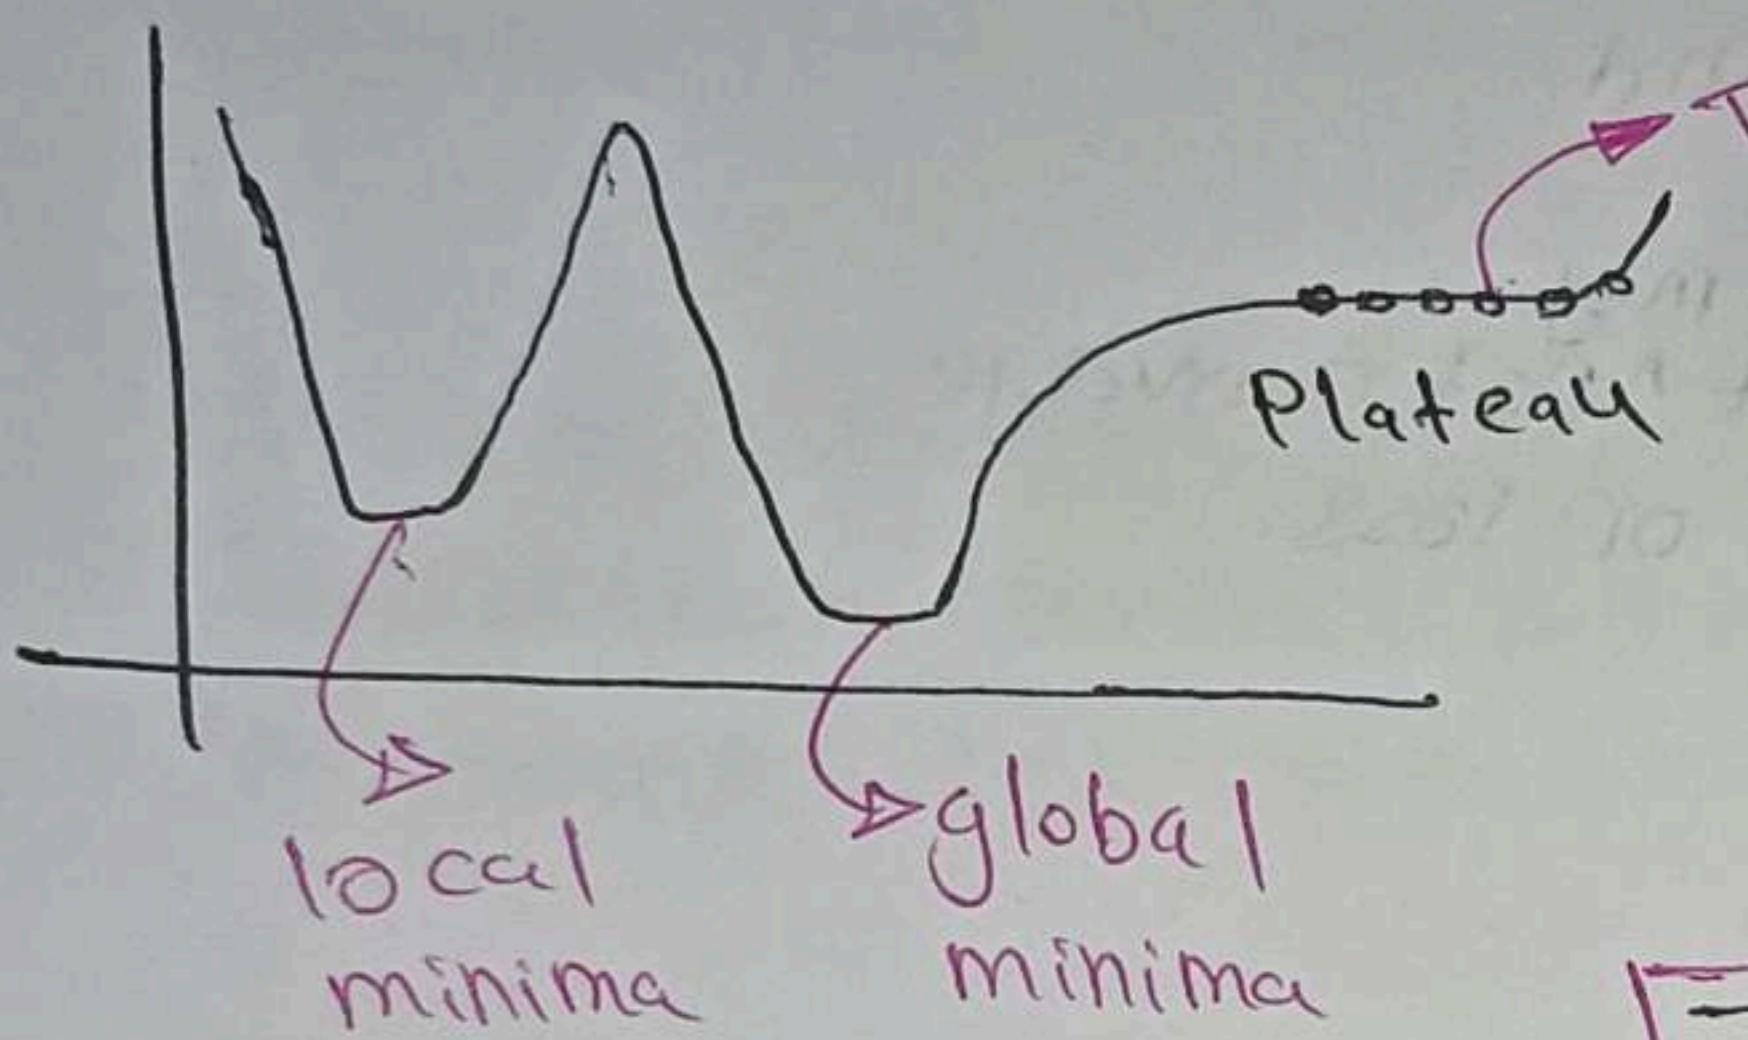

Giga	I	gender	Cpa
------	---	--------	-----

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3$$

* In Non Convex function there are two problems

- ①
 - local minima is here: → our algo. converge here and we should not go anywhere.
 - more than 2 minima & Solution may be converge on local minima.

② Plateau:-

In 3D Plateau become Saddle Point

only name change
idea is same

* Effect of Data:

- If data is well scaled then our algorithm will fast converge towards the minima.

- ② Moderate LR:
- Give optimize result
 - Not want more number of epochs
 - Get faster result

- ① High LR:
- It get bigger and bigger step.

• And sometimes it ^{may} not converge to minimum value of loss.

② Effect of loss function:

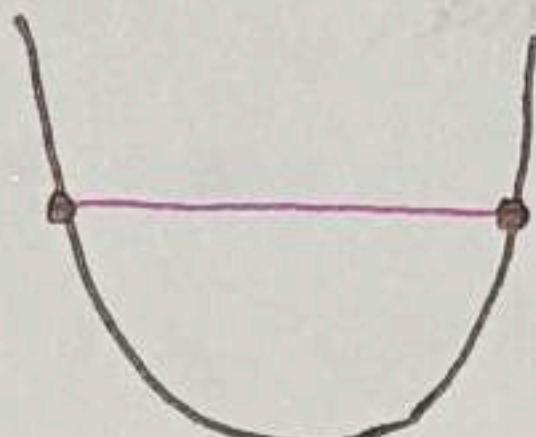

$$L = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

→ this loss function is convex function

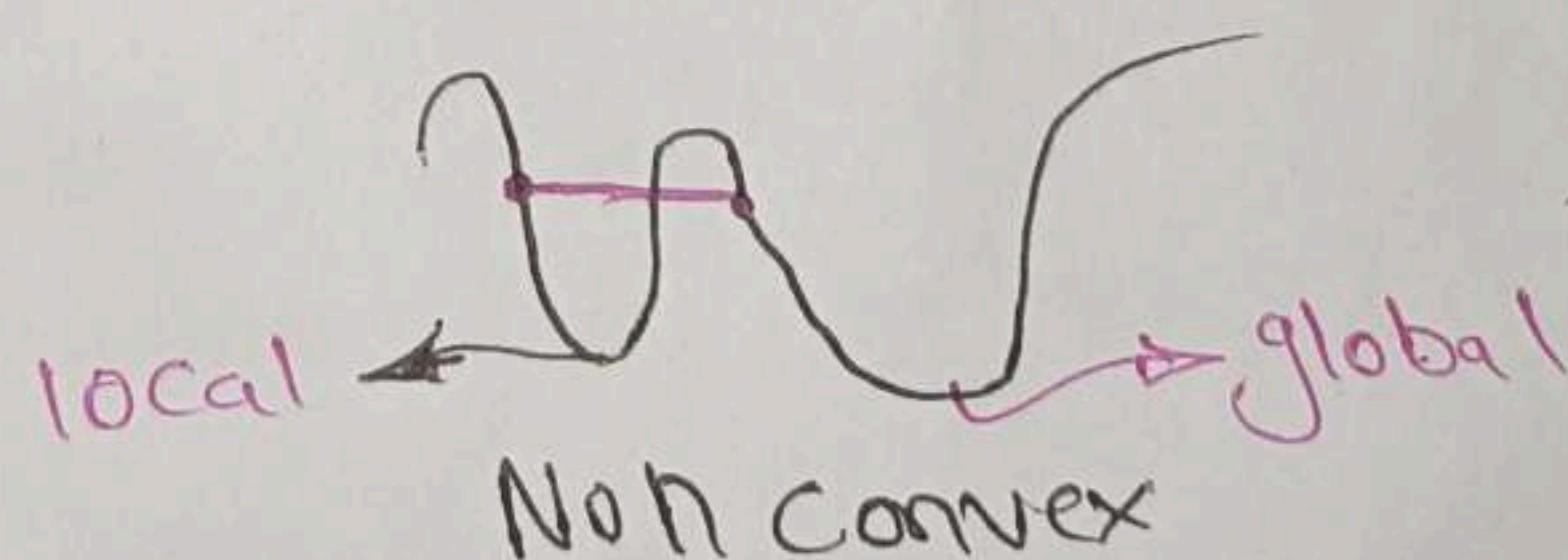

* Now what is convex function

• If we draw a line between two points that line never cross the function that function is called convex function.

Ex:

Non convex Ex:-

• In convex function there is only one minima and that is global minima

• In non convex function there is more than one minima we called them global minima and local minima.

ALSO Making Function to Predict

```
def Predict(self, x)  
    return self.m * x + self.b
```

```
from sklearn.model_selection import train_test_split
```

```
X-train, X-test, Y-train, Y-test = train_test_split(X, Y, test_size=0.2, random_state=2)
```

```
Y-Pred = lr.Predict(X-test)
```

```
from sklearn.metrics import r2_score
```

```
r2-score(Y-test, Y-Pred)
```

→ 0.63 → this is ~~before class~~

Now

```
gd.fit(X-train, Y-train)
```

```
Pred = gd.Predict(X-test)
```

```
from sklearn.metrics import r2_score
```

```
r2-score(Y-test, Y-Pred)
```

→ 0.63 → our class result

* Impact on gradient Descent of HyperParameter, loss Func & Data.

① learning rate

② loss function

③ Data

① learning rate:

• low LR: • If LR is 0.002

• very small steps are getting

• more epoch value

• not much optimize

Class GDRegressor:

```
def __init__(self, learning_rate=0.01, epochs=100):
    self.coef_ = None
    self.intercept_ = None
    self.lr = learning_rate
    self.epochs = epochs.
```

```
def fit(self, X_train, y_train):
```

```
    self.intercept_ = 0
```

```
    self.coef_ = np.ones(X_train.shape[1])range
```

```
    for i in (self.epochs):
```

Updating all the Coef & Intercept

First understand the intercept - formula.

$$\frac{\partial L}{\partial \beta_0} = -\frac{2}{n} \sum_{i=1}^n (y_i - \hat{y}_i)$$

$(y_i - \hat{y}_i) \rightarrow n$ This is nothing
but our y-train

$$= -\frac{2}{n} \sum_{i=1}^n \star \quad \text{This is nothing
but formula for calculating
mean.}$$

Understand calculation to

$x_1 | x_2 | x_3 | y$ finding \hat{y} hat

- | - | - | - for first row

$$\hat{y}_1 = \beta_0 + \beta_1 x_{11} + \beta_2 x_{12} + \beta_3 x_{13}$$

$$\hat{y}_2 = \beta_0 + \beta_1 x_{21} + \beta_2 x_{22} + \beta_3 x_{23}$$

$$\hat{y}_i = \beta_0 + [x_{i1} x_{i2} x_{i3}] \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix},$$

we can calculate for
all values in
 x_{train}
by using vectorization

$$\hat{y} = \beta_0 + \text{np.dot}(coef_, x_{train})$$

Formula becomes $\beta_0 + \text{np.dot}(x_{train}, coef_*)$
(353, 10) (10, 1)
 $x_{train}.shape$ $coef_.shape$ (353, 1) ***

* Now calculating of β_1 , slope *

$$L = \frac{1}{2} \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

$$L = \frac{1}{2} [(y_1 - \hat{y}_1)^2 + (y_2 - \hat{y}_2)^2]$$

$$L = \frac{1}{2} [(y_1 - \beta_0 - \beta_1 x_{11} - \beta_2 x_{12})^2 + (y_2 - \beta_0 - \beta_1 x_{21} - \beta_2 x_{22})^2]$$

$$\frac{\partial L}{\partial \beta_1} = \frac{1}{2} [2(y_1 - \hat{y}_1)(-x_{11}) + 2(y_2 - \hat{y}_2)(-x_{21})]$$

$$\boxed{\frac{\partial L}{\partial \beta_1} - \beta_1 x_{11} = -x_{11}}$$

$$\frac{\partial L}{\partial \beta_1} = \frac{-2}{n} [(y_1 - \hat{y}_1)(x_{11}) + (y_2 - \hat{y}_2)(x_{21}) + (y_3 - \hat{y}_3)(x_{31}) + \dots + (y_n - \hat{y}_n)(x_{n1})]$$

$$\boxed{\frac{\partial L}{\partial \beta_1} = \frac{-2}{n} \sum_{i=1}^n (y_i - \hat{y}_i) x_{i1}}$$

x_1	x_2	y
8.1	93	3.2
7.5	95	3.5

x_{i1} is to represent all values
of Column 1

$$\boxed{\frac{\partial L}{\partial \beta_2} = \frac{-2}{n} \sum_{i=1}^n (y_i - \hat{y}_i) x_{i2}}$$

* For m cols *

$$\boxed{\frac{\partial L}{\partial \beta_m} = \frac{-2}{n} \sum_{i=1}^n (y_i - \hat{y}_i) x_{im}}$$

$$L = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad \left\{ \text{rows} = 2, \text{cols} = 2+3 \right\}$$

(MSE)

$$= \frac{1}{2} [(y_1 - \hat{y}_1)^2 + (y_2 - \hat{y}_2)^2]$$

$$\hat{y}_i = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i}$$

$$\hat{y}_1 = \beta_0 + \beta_1 x_{11} + \beta_2 x_{12}$$

$$\hat{y}_2 = \beta_0 + \beta_1 x_{21} + \beta_2 x_{22}$$

x_{11}	x_{12}	y
8.1	9.3	3.2
7.5	9.5	3.5
		9.6
x_{21}	x_{22}	

Annotations: $\rightarrow y_1$, $\rightarrow y_2$

$$= \frac{1}{2} [(y_1 - (\beta_0 + \beta_1 x_{11} + \beta_2 x_{12}))^2 + (y_2 - (\beta_0 + \beta_1 x_{21} + \beta_2 x_{22}))^2]$$

$$\frac{\partial L}{\partial \beta_0} = \frac{1}{2} [2(y_1 - \hat{y}_1) + 2(y_2 - \hat{y}_2) - 1]$$

$$\frac{\partial L}{\partial \beta_0} = -\frac{2}{n} [(y_1 - \hat{y}_1) + (y_2 - \hat{y}_2)]$$

for N rows

$$\frac{\partial L}{\partial \beta_0} = -\frac{2}{n} [(y_1 - \hat{y}_1) + (y_2 - \hat{y}_2) + (y_3 - \hat{y}_3) + \dots + (y_n - \hat{y}_n)]$$

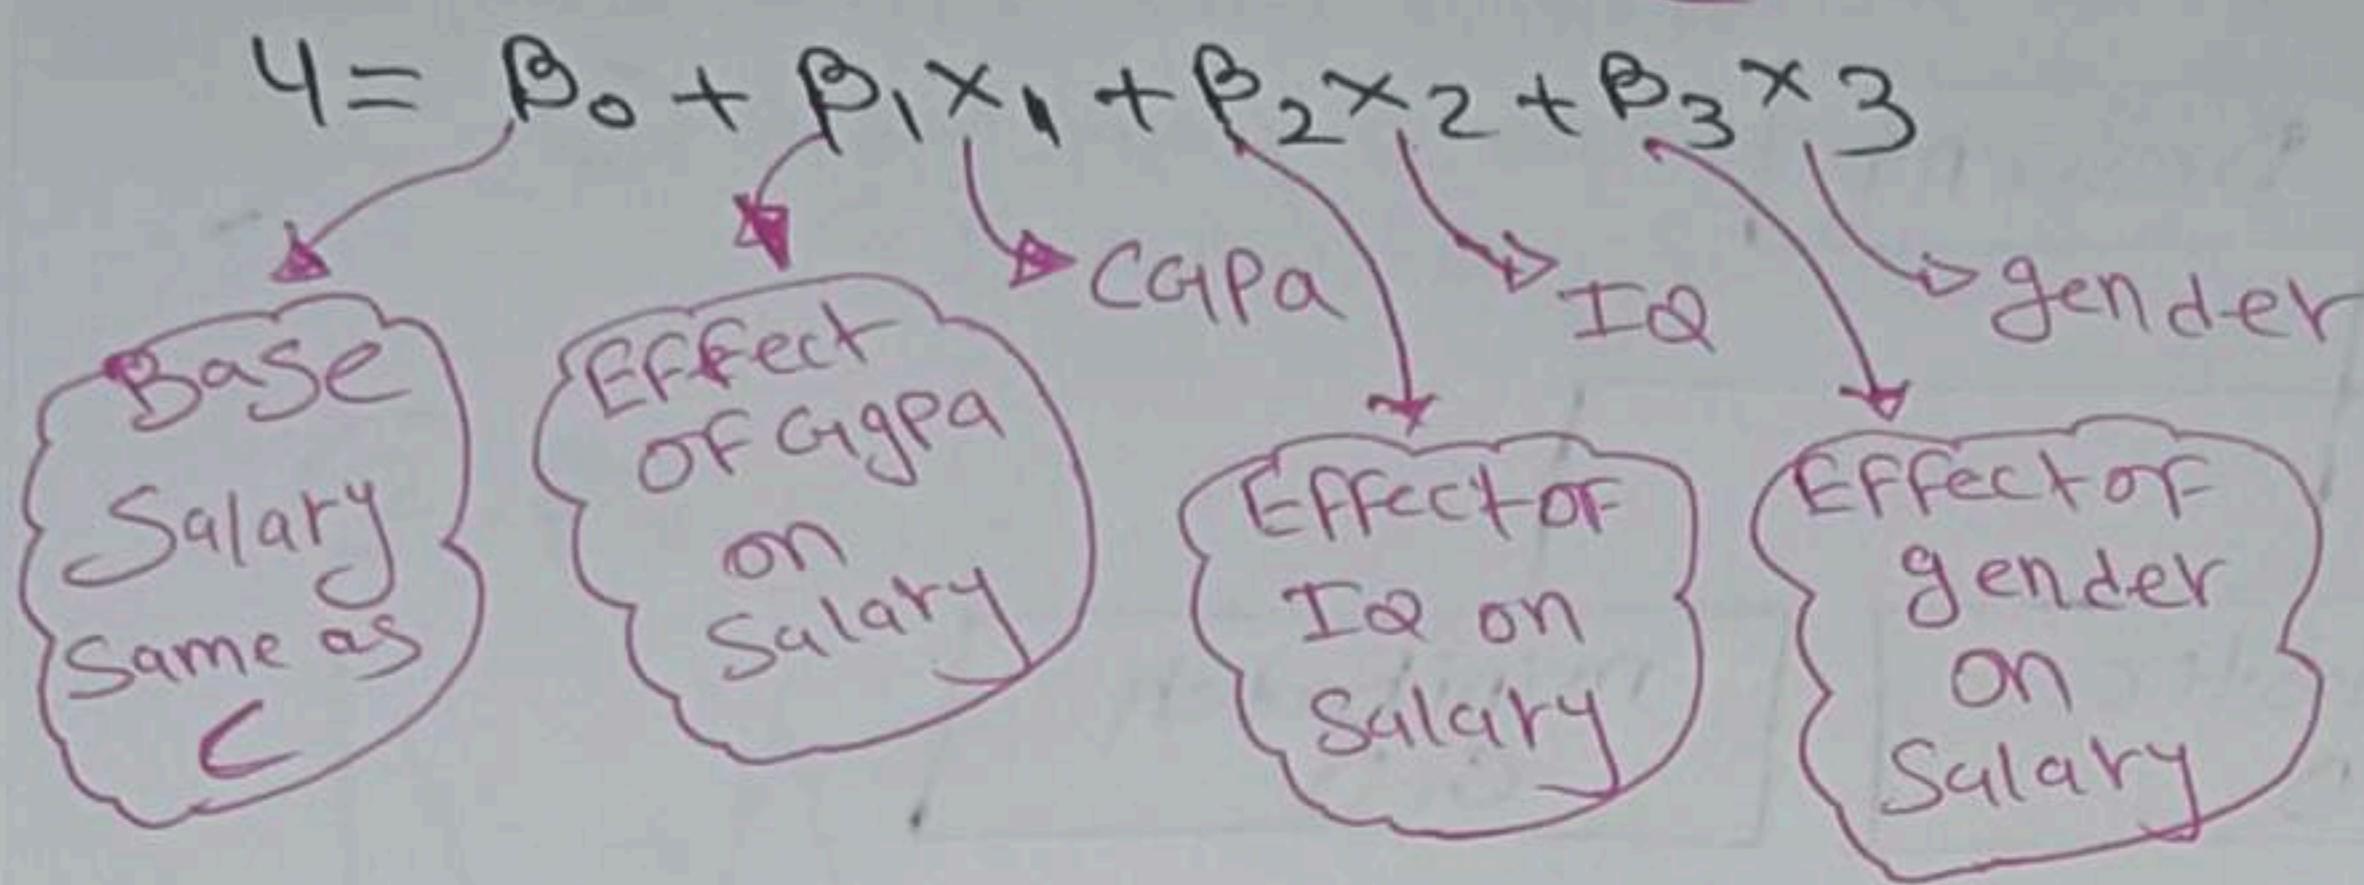

$$\frac{\partial L}{\partial \beta_0} = -\frac{2}{n} \sum_{i=1}^n (y_i - \hat{y}_i)$$

→ This is give the value of slope

$$\beta_0 = \beta_0 - n \text{ Slope}$$

→ This value is calculated by $\frac{\partial L}{\partial \beta_0}$

Understand the equation

N Dimensional Data

$$\{\beta_0, \beta_1, \beta_2, \dots, \beta_n\}$$

Values required to find the value of y predict

Mathematical formulation

CGPA | IQ | IPG

x_1	x_2	y
8.1	93	3.2
7.5	95	3.5

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2$$

(IPG) (CGPA) (IPG)

Step 1: Start with random value

generally $\beta_0 = 0, \beta_1, \beta_2 = 1$

Step 2: Epoch = 100, lr = 0.1

$$\beta_0 = \beta_0 - n \text{slope} \rightarrow \frac{\partial L}{\partial \beta_0}$$

$$\beta_1 = \beta_1 - n \text{slope} \rightarrow \frac{\partial L}{\partial \beta_1}$$

$$\beta_2 = \beta_2 - n \text{slope} \rightarrow \frac{\partial L}{\partial \beta_2}$$

$L(\beta_0, \beta_1, \beta_2)$

Intercept

* In Batch gradient descent value of coef. is change after checking full data. only one time changes

* In Stochastic we change value of coef. by seeing/checking a single row.

→ row update

* In 1 single epoch n updates will do

- faster convergence
- row is select randomly
- Not give steady (ans) soln

* Now, coding Part *

$$6000 \times 50 \rightarrow 300000$$

derivatives
want to calculate

- ① It makes algorithm slow

→ Deep learning

→ CNN → Images } Both are

→ RNN → Text } high dimensional Data

- * And In Deep Learning most of the time we are not use Batch GD

In Coding Part we did vectorization to calculate \hat{y} .

$$\hat{y} = \text{np.dot}(x_train, \text{self.coef_}) + \text{self.intercept_}$$

In this we used numpy and avoid loop

* When we are calculating \hat{y} we load full x_train data load on RAM.

* And if data is very large then it could give error Not exactly error but system not support (Hardware Problem)

* To resolve this all Problem we shifted toward Stochastic GD

$$\text{Coef_der} = -2 * \text{np}.dot((y-\text{train} - y\text{-hat}), x\text{-train}) / x\text{-train.shape[0]}$$

$$\text{self.coef_} = \text{self.coef_} - (\text{self.lr} * \text{coef_der})$$

def Predict(self, x-test):

return np.dot(x-test, self.coef_) + self.intercept_

gdr = GDRegressor (epochs=100, learning-rate=0.5)

gdr.fit(x-train, y-train)

$$152.0135 [14.3891 \quad -173.72 \quad 491.54 \quad 323.91, \\ -39.32 \quad -116.010. \quad -194.04 \quad 103.38 \\ 451.63 \quad 97.57]$$

y_Pred = gdr.Predict(x-test)

r₂-score(y-test, y-Pred)

0.45

$$\hat{y} = \text{np.dot}(x_train, \text{self.coef_}) + \text{self.intercept_}$$

$$\text{Intercept_der} = -2 * \text{np.mean}(y_train - \hat{y})$$

$$\text{self.intercept_} = \text{self.intercept_} - (\text{self.it} * \text{intercept_der})$$

Now time to calculate coef-

for single:

$$\frac{\partial L}{\partial \beta_1}, \frac{\partial L}{\partial \beta_2}, \frac{\partial L}{\partial \beta_n}$$

* How to find out this opt game time?

$$\frac{\partial L}{\partial \beta_1} = -\frac{2}{n} \sum_{i=1}^n (y_i - \hat{y}_i) x_{i1}$$

x_1	x_2	y	\hat{y}
1	2	5	6
3	4	7	8

$$[5 \ 7] \hat{[6 \ 8]}$$

$$y - \hat{y} = [-1, -1]$$

$$[-1, -1] [1 \ 3]$$

$$[(y - \hat{y}) \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix}] \times -\frac{2}{n}$$

$$[-4 + -8] \\ (-8)$$

$$\frac{\partial L}{\partial \beta_1} = \dots \frac{\partial L}{\partial \beta_{10}},$$

$$= [(y_i - \hat{y}_i) \times \text{train}] \times -\frac{2}{n}$$

$$(353, 1)^T \quad (353, 10)$$

$$(1, 353) \quad (353, 10)$$

$$(1, 10) \times -\frac{2}{n} = (1, 10) \rightarrow \text{coef_der}$$

$$y_{\text{pred}} = \text{reg. predict}(x_{\text{test}})$$

$$r^2\text{-score}(y_{\text{test}}, y_{\text{pred}})$$

→ 0.439938

Now we make our class to predict coefficient

Class SGDRegressor:

```
def __init__(self, learning_rate=0.01, epochs=100):
    self.coef_ = None
```

self.intercept_ = None

self.lr = learning_rate

self.epochs = epochs

```
def fit(self, x_train, y_train):
```

self.intercept_ = 0

self.coef_ = np.ones(x_train.shape[1])

for i in range(self.epochs):

for j in range(x_train.shape[0]):

idx = np.random.randint(0, x_train.shape[0])

$\hat{y} = \text{np.dot}(x_{\text{train}}[\text{idx}], \text{self.coef}) + \text{self.intercept}$

In BGD

$$\frac{\partial L}{\partial \beta_0} = -2 \frac{m}{m} \sum_{i=1}^m (y_i - \hat{y}_i)$$

1

collectively

Not required in SGD

for SGD

$$\frac{\partial L}{\partial \beta_0} = -2(y_i - \hat{y}_i)$$

$$\text{intercept_det} = -2 * (y_{\text{train}}[\text{idx}] - \hat{y}_{\text{train}})$$

$$\text{self.intercept_} = \text{self.intercept_} - (\text{self.lr} * \text{intercept_det})$$

Coef-det.

$$\frac{\partial L}{\partial \beta_i} = -\frac{2}{n} \sum_{i=1}^n (y_i - \hat{y}_i) x_{i1}$$

In BatchGD

$$\frac{\partial L}{\partial \beta_i} = -2 (y_i - \hat{y}_i) x_{ii}$$

$$\text{Coef-det} = -2 * ((y_{\text{train}}[\text{idx}] - \hat{y}), x_{\text{train}}[\text{idx}])$$
$$\text{Self-coef} = \text{Self.coef} - (\text{self.lr} * \text{Coef-det})$$

$x_{\text{train}}.\text{shape}$
 $\rightarrow (353, 10)$

* Rule of matrix multiplication *

A $\rightarrow (m \times n)$ shape

B $\rightarrow (n \times p)$ shape

C $\rightarrow (m \times p)$ shape

$$(353, 10) * (1, 1) = (10)$$

* In this SGD Algorithm we converge to our minimum loss value by giving less number of epochs.

Sgd = SGDRegressor(learning_rate=0.01, epochs=50)

Sgd.fit(x_train, y_train)

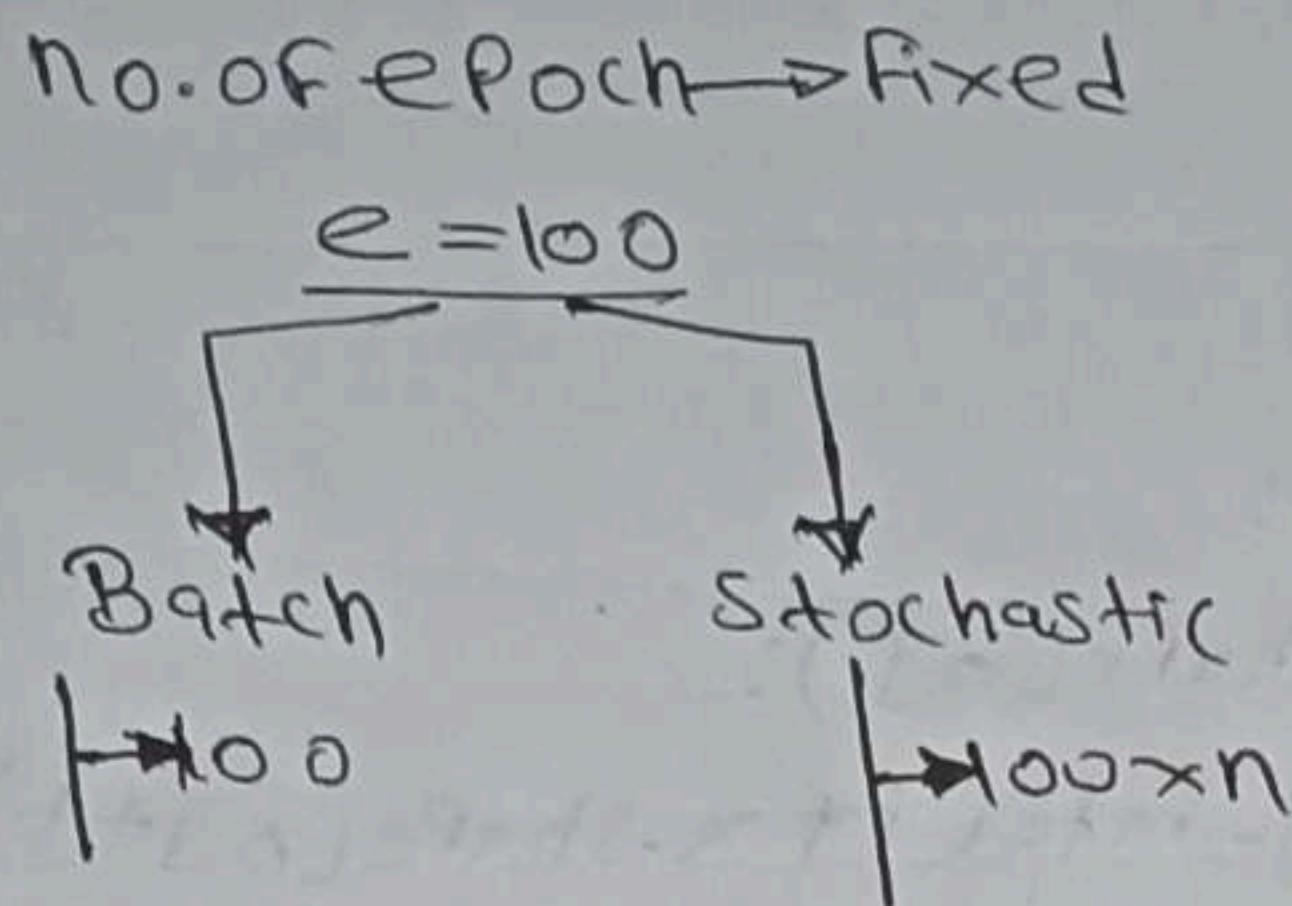

$\rightarrow [150.83, 8 [54.28, -67.43, 851.20, 251.58, 17.26, -28.74, -165.85, 123.27, 314.84, 123.52]]$

y_Pred = Sgd.predict(x_test)

r2-score(y_test, y_Pred)

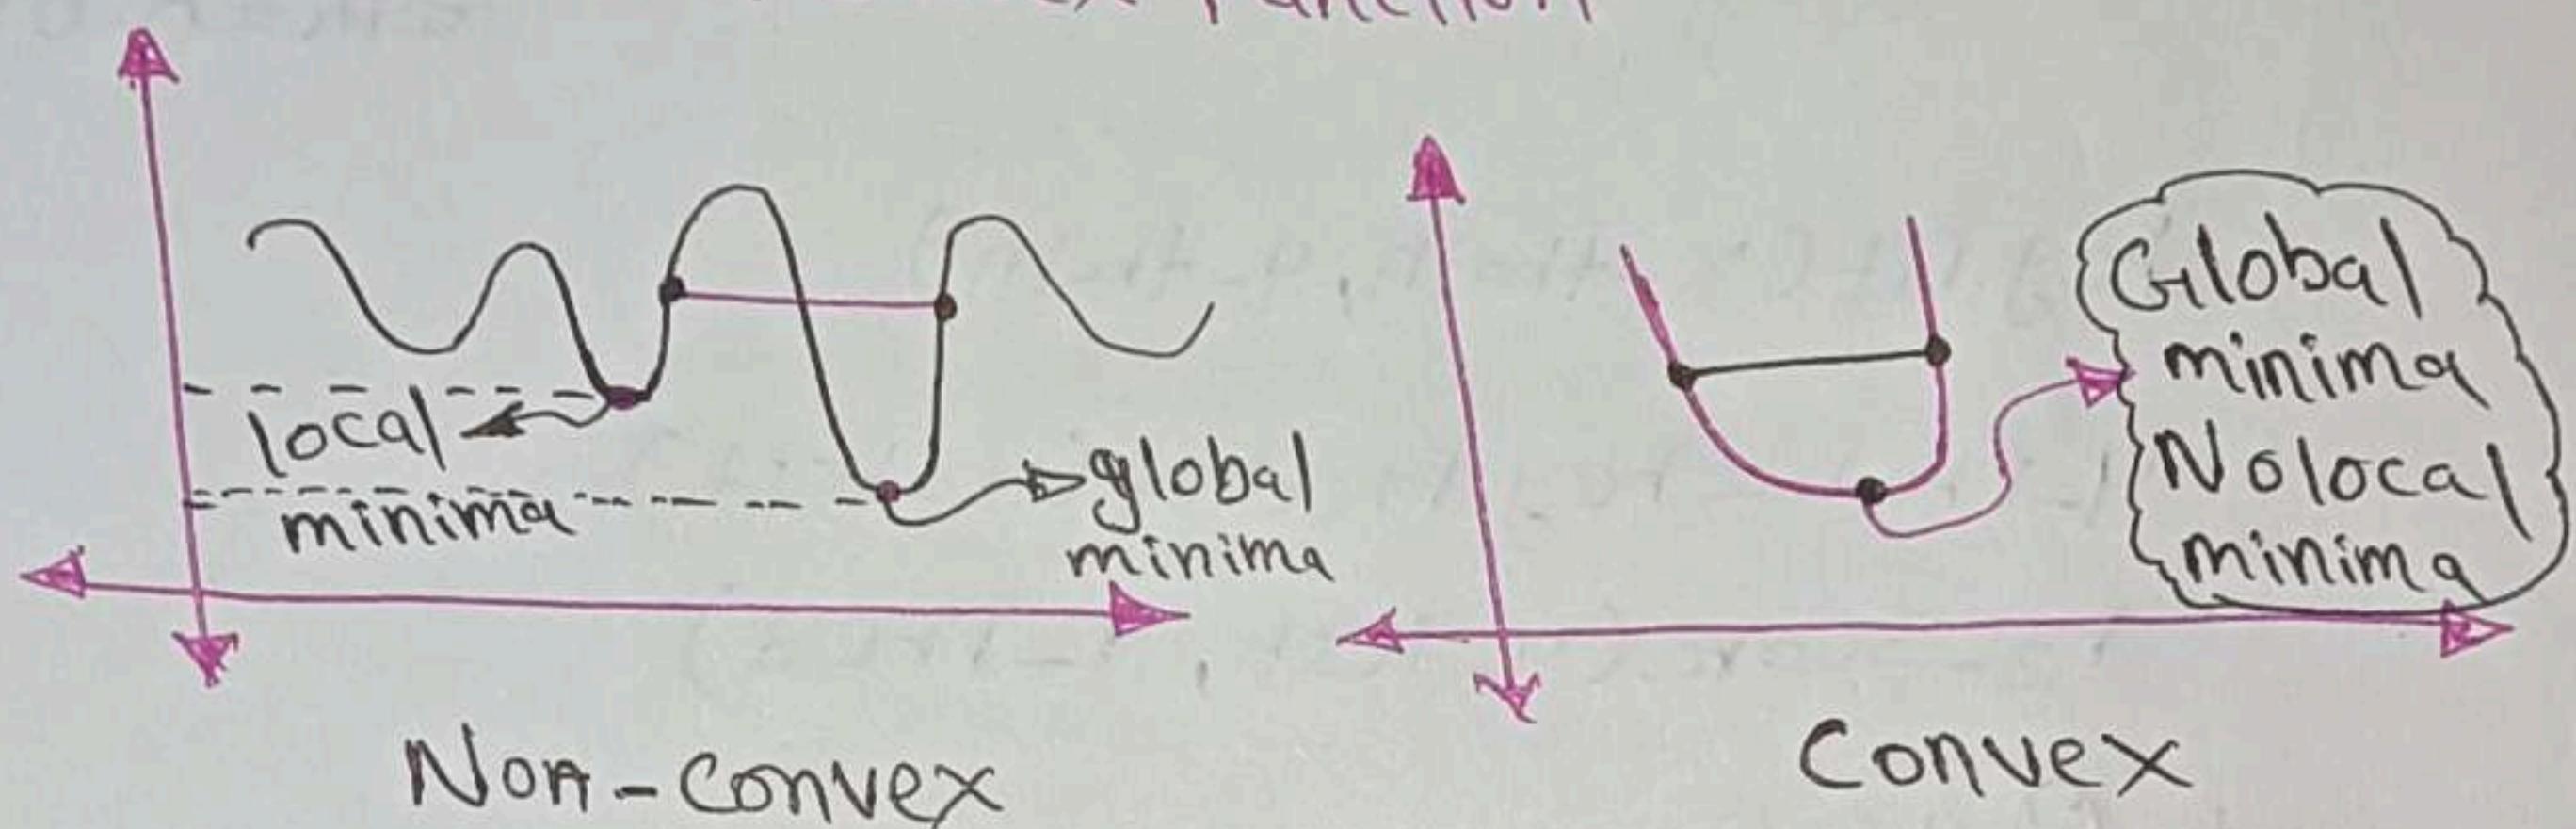

$\rightarrow 0.4325$

* Time comparison

* When to use Stochastic GD

- ① Big data
- ② When we have non convex function

* Because of stochastic nature of SGD it could be ~~how get out~~ from local minima (It haven't velocity which is not stop it to local minima.)

* Problem with SGD

① In Stochastic GD, even after reaching the optimal solution, the algorithm continues to update parameters and does not stop exactly at the minimum.

* To solve this problem we use one concept called learning schedule.

* Learning Schedule: Learning rate schedule is a strategy in machine learning where the learning rate is changed (usually reduced) during training instead of keeping it constant, so that the model learn fast at the beginning and converges smoothly later.

$$y_{\text{hat}} = \text{np.dot}(x_{\text{train}}[:, \text{idx}], \text{self.coef_}) + \text{self.intercept_}$$

$$\text{intercept_der} = -2 * \text{np.mean}(y_{\text{train}}[:, \text{idx}] - y_{\text{hat}})$$

$$\text{coef_der} = -2 * \text{np.dot}((y_{\text{train}}[:, \text{idx}] - y_{\text{hat}}), x_{\text{train}}[:, \text{idx}])$$

$$\text{self.coef_} = \text{self.coef_} - (\text{self.lr} * \text{coef_der})$$

Print(self.intercept_, self.coef_)
